# On Sherman-Steffensen Type Inequalities

## Marek Niezgoda<sup>a</sup>

<sup>a</sup> Department of Applied Mathematics and Computer Science, University of Life Sciences in Lublin, Akademicka 13, 20-950 Lublin, Poland

**Abstract.** In this work, Sherman-Steffensen type inequalities for convex functions with not necessary non-negative coefficients are established by using Steffensen's conditions. The Brunk, Bellman and Olkin type inequalities are derived as special cases of the Sherman-Steffensen inequality. The superadditivity of the Jensen-Steffensen functional is investigated via Steffensen's condition for the sequence of the total sums of all entries of the involved vectors of coefficients. Some results of Barić et al. [2] and of Krnić et al. [11] on the monotonicity of the functional are recovered. Finally, a Sherman-Steffensen type inequality is shown for a row graded matrix.

### 1. Preliminaries and motivation

The celebrated *weighted Jensen's inequality* [5, 14, 18] claims that if f is a real convex function defined on an interval  $I \subset \mathbb{R}$ , and real coefficients  $p_1, p_2, \ldots, p_n$  are such that

$$p_i \ge 0, \quad i = 1, 2, ..., n, \quad \text{and} \quad P_n = p_1 + p_2 + ... + p_n > 0$$
 (1)

then, for any  $x_1, x_2, \ldots, x_n \in I$ ,

$$f\left(\frac{1}{P_n}\sum_{i=1}^n p_i x_i\right) \le \frac{1}{P_n}\sum_{i=1}^n p_i f(x_i). \tag{2}$$

**Theorem A.** (Steffensen [21].) Assume that f is a real convex function defined on an interval  $I \subset \mathbb{R}$ . Let  $w_1, w_2, \ldots, w_n \in \mathbb{R}$ . Denote  $W_i = w_1 + w_2 + \ldots + w_i$  for  $i = 1, 2, \ldots, n$ .

$$W_n \ge W_i \ge 0$$
,  $i = 1, 2, ..., n$ , and  $W_n > 0$  (Steffensen's condition), (3)

then, for any monotonic n-tuple  $\mathbf{x} = (x_1, x_2, \dots, x_n) \in I^n$ ,

$$f\left(\frac{1}{W_n}\sum_{i=1}^n w_i x_i\right) \le \frac{1}{W_n}\sum_{i=1}^n w_i f(x_i). \tag{4}$$

Inequality (4) admitting (not necessary non-negative) weights  $w_i$  and satisfying Steffensen's condition (3) is called *Jensen-Steffensen inequality* [1].

Keywords. convex function, Jensen-Steffensen's inequality, Jensen-Steffensen's functional, Sherman-Steffensen's inequality, column stochastic matrix, doubly stochastic matrix, row graded matrix

**Example 1.1.** Suppose that  $f: I \to \mathbb{R}$  is convex on an interval  $I = [0, x_1]$  with  $f(0) \le 0$ , and  $x_1 \ge x_2 \ge ... \ge x_n \ge 0$ .

Brunk inequality [6] asserts that for

$$1 \ge h_1 \ge h_2 \ge \dots \ge h_n \ge 0,\tag{5}$$

it holds that

$$f\left(\sum_{i=1}^{n} (-1)^{i-1} h_i x_i\right) \le \sum_{i=1}^{n} (-1)^{i-1} h_i f(x_i). \tag{6}$$

A special case of inequality (6) for  $h_1 = h_2 = ... = h_n = 1$  is *Bellman's inequality* (see [3, p. 462]). In fact, by considering the (n + 1)-vector  $(x_1, ..., x_n, 0)$  and the (n + 1)-sequence of weights

$$\left(h_1, -h_2, h_3, -h_4, \dots (-1)^{n-1}h_n, 1 - \sum_{i=1}^n (-1)^{i-1}h_i\right),$$

we see from (3) that Steffensen's condition is fulfilled. So, it now follows from inequality (4) in Theorem A that

$$f\left(\sum_{i=1}^{n} (-1)^{i-1} h_i x_i + \left(1 - \sum_{i=1}^{n} (-1)^{i-1} h_i\right) \cdot 0\right)$$

$$\leq \sum_{i=1}^{n} (-1)^{i-1} h_i f(x_i) + \left(1 - \sum_{i=1}^{n} (-1)^{i-1} h_i\right) f(0)$$

$$\leq \sum_{i=1}^{n} (-1)^{i-1} h_i f(x_i),$$

since  $f(0) \le 0$  and  $1 - \sum_{i=1}^{n} (-1)^{i-1} h_i \ge 0$  (see (5)).

We finish this example by the remark that resignation from the assumption  $f(0) \le 0$  leads to the first above inequality only, which is a result due to Olkin [17].

We return to relevant notation, definitions and theorems.

Let  $f: I \to \mathbb{R}$  be a function on an interval  $I \subset \mathbb{R}$ ,  $\mathbf{x} = (x_1, x_2, \dots, x_n) \in I^n$  and  $\mathbf{p} \in \mathcal{P}_n^0$ , where

$$\mathcal{P}_n^0 = \{ \mathbf{p} = (p_1, p_2, \dots, p_n) \in \mathbb{R}^n : p_i \ge 0, P_n > 0 \} \text{ with } P_n = \sum_{i=1}^n p_i.$$

The Jensen functional is defined by (see [8])

$$J(f, \mathbf{x}, \mathbf{p}) = \sum_{i=1}^{n} p_i f(x_i) - P_n f\left(\frac{1}{P_n} \sum_{i=1}^{n} p_i x_i\right).$$
 (7)

Equivalently,

$$J(f, \mathbf{x}, \mathbf{p}) = \langle \mathbf{p}, f(\mathbf{x}) \rangle - \langle \mathbf{p}, \mathbf{e} \rangle f\left(\frac{\langle \mathbf{p}, \mathbf{x} \rangle}{\langle \mathbf{p}, \mathbf{e} \rangle}\right),\tag{8}$$

where  $\langle \cdot, \cdot \rangle$  is the standard inner product on  $\mathbb{R}^n$ ,  $\mathbf{e} = (1, 1, ..., 1) \in \mathbb{R}^n$ ,  $\mathbf{x} = (x_1, x_2, ..., x_n) \in I^n$  and  $f(\mathbf{x}) = (f(x_1), f(x_2), ..., f(x_n))$ .

By Jensen's inequality,

 $J(f, \mathbf{x}, \mathbf{p}) \ge 0$  for a convex function f.

**Theorem B. [8]** If  $f: I \to \mathbb{R}$  is a convex function then the function  $\mathbf{p} \to J(f, \mathbf{x}, \mathbf{p})$ ,  $\mathbf{p} \in \mathcal{P}_n^0$ , is superadditive for any  $\mathbf{x} \in I^n$ , i.e.,

$$J(f, \mathbf{x}, \mathbf{p} + \mathbf{q}) \ge J(f, \mathbf{x}, \mathbf{p}) + J(f, \mathbf{x}, \mathbf{q}) \quad \text{for } \mathbf{p}, \mathbf{q} \in \mathcal{P}_n^0.$$
(9)

In consequence, the function  $\mathbf{p} \to J(f, \mathbf{x}, \mathbf{p}), \mathbf{p} \in \mathcal{P}_n^0$ , is monotone for any  $\mathbf{x} \in I^n$ , i.e.,

$$\mathbf{q} \le \mathbf{p}$$
 implies  $J(f, \mathbf{x}, \mathbf{q}) \le J(f, \mathbf{x}, \mathbf{p})$  for  $\mathbf{q}, \mathbf{p} - \mathbf{q} \in \mathcal{P}_n^0$ . (10)

See [12] for some refinements and converses of the Jensen inequality obtained with the help of Theorem B [8].

We say that a vector  $\mathbf{y} = (y_1, y_2, \dots, y_n) \in \mathbb{R}^n$  is majorized by a vector  $\mathbf{x} = (x_1, x_2, \dots, x_n) \in \mathbb{R}^n$ , written as  $\mathbf{y} < \mathbf{x}$ , if

$$\sum_{i=1}^{k} y_{[i]} \le \sum_{i=1}^{k} x_{[i]} \quad \text{for } k = 1, 2, \dots, n$$

with equality for k = n, where the symbols  $x_{[i]}$  and  $y_{[i]}$  denote the ith largest entry of  $\mathbf{x}$  and  $\mathbf{y}$ , respectively (see [13, p. 8]).

An  $n \times m$  real matrix  $\mathbf{S} = (s_{ij})$  is called *column stochastic* if  $s_{ij} \ge 0$  for i = 1, 2, ..., n, j = 1, 2, ..., m, and all column sums of  $\mathbf{S}$  are equal to 1, i.e.,  $\sum_{i=1}^{n} s_{ij} = 1$  for j = 1, 2, ..., m. If in addition m = n and the transpose  $\mathbf{S}^T = (s_{ij})$  of  $\mathbf{S} = (s_{ij})$  is column stochastic, then  $\mathbf{S}$  is called *doubly stochastic*.

An important relationship between majorization and double stochasticity is the following (see [13, p. 33]): for  $x, y \in \mathbb{R}^n$ ,

$$\mathbf{y} < \mathbf{x}$$
 if and only if  $\mathbf{y} = \mathbf{x}\mathbf{S}$  for some doubly stochastic  $n \times n$  matrix  $\mathbf{S}$ . (11)

The next result is called *Majorization Theorem* (see [13, pp. 92-93]).

**Theorem C.** (Schur [20], Hardy-Littlewood-Pólya [9] and Karamata [10].) *Assume that f is a real convex function defined on an interval*  $I \subset \mathbb{R}$ .

Then, for  $\mathbf{x} = (x_1, x_2, ..., x_n) \in I^n$  and  $\mathbf{y} = (y_1, y_2, ..., y_n) \in I^n$ ,

$$\mathbf{y} < \mathbf{x} \quad implies \quad \sum_{i=1}^{n} f(y_i) \le \sum_{i=1}^{n} f(x_i). \tag{12}$$

In [15] the author showed Sherman - Steffensen inequality (15) with non-negative coefficients  $b_j$  and with not necessary non-negative matrix S.

**Theorem D.** (Niezgoda [15].) Let  $f: I \to \mathbb{R}$  be a convex function defined on an interval  $I \subset \mathbb{R}$ . Let  $\mathbf{x} = (x_1, x_2, \dots, x_n) \in I^n$ ,  $\mathbf{y} = (y_1, y_2, \dots, y_m) \in I^m$ ,  $\mathbf{a} = (a_1, a_2, \dots, a_n) \in \mathbb{R}^n$  and  $\mathbf{b} = (b_1, b_2, \dots, b_m) \in \mathbb{R}^m$ . Assume that  $\mathbf{x}$  is monotonic.

If

$$\mathbf{y} = \mathbf{x}\mathbf{S} \quad and \quad \mathbf{a} = \mathbf{b}\mathbf{S}^T \tag{13}$$

for some  $n \times m$  matrix  $\mathbf{S} = (s_{ij})$  such that for each j = 1, ..., m,

$$0 \le S_{ij} \le S_{nj} = 1 \quad \text{for } i = 1, \dots, n,$$
 (14)

where  $S_{ij} = \sum_{k=1}^{i} s_{kj}$ , then

$$\sum_{j=1}^{m} b_j f(y_j) \le \sum_{i=1}^{n} a_i f(x_i). \tag{15}$$

In the case of non-negative entries of **S** with total sums  $S_{nj} = 1$ , j = 1, ..., m, condition (14) can be removed and then Theorem D becomes Sherman's Theorem [19].

Some applications of Sherman's Theorem can be found in [4, 7, 15, 16].

**Remark 1.2.** It is not hard to check that Jensen - Steffensen's inequality (4) is a special form of Sherman - Steffensen's inequality (15) with m = 1 and  $b_1 = 1$ .

For  $\mathbf{b} = (1, 1, ..., 1) \in \mathbb{R}^m_+$ , inequality (15) yields

$$\sum_{j=1}^m f(y_j) \le \sum_{i=1}^n a_i f(x_i),$$

where  $a_i = \sum_{j=1}^m s_{ij}$  is the *i*th row sum of **S**, i = 1, ..., n.

For instance, if  $a_i = \sum_{j=1}^m s_{ij} = 1$  for i = 1, ..., n, then m = n and the last inequality takes the form of HLPK inequality (12).

**Example 1.3.** Suppose that  $f: I \to \mathbb{R}$  is convex on an interval  $I = [0, x_1]$  with  $f(0) \le 0$ , and  $\mathbf{x} = (x_1, x_2, \dots, x_n)$  with  $x_1 \ge x_2 \ge \dots \ge x_n \ge 0$ , and  $b_1, \dots, b_m$  are non-negative coefficients.

$$\mathbf{H} = \begin{pmatrix} h_{11} & h_{12} & \cdots & h_{1m} \\ h_{21} & h_{22} & \cdots & h_{2m} \\ \vdots & \vdots & \cdots & \vdots \\ h_{n1} & h_{n2} & \cdots & h_{nm} \end{pmatrix}$$

be an  $n \times m$  real matrix such that

$$1 \ge h_{1j} \ge h_{2j} \ge \dots \ge h_{nj} \ge 0 \quad \text{for } j = 1, \dots, m.$$
 (16)

Consider the  $(n + 1) \times m$  matrix

$$\mathbf{S} = \begin{pmatrix} h_{11} & h_{12} & \cdots & h_{1m} \\ -h_{21} & -h_{22} & \cdots & -h_{2m} \\ h_{31} & h_{32} & \cdots & h_{3m} \\ -h_{41} & -h_{42} & \cdots & -h_{4m} \\ \vdots & \vdots & \ddots & \vdots \\ (-1)^{n-1}h_{n1} & (-1)^{n-1}h_{n2} & \cdots & (-1)^{n-1}h_{nm} \\ 1 - \sum_{i=1}^{n} (-1)^{i-1}h_{i1} & 1 - \sum_{i=1}^{n} (-1)^{i-1}h_{i2} & \cdots & 1 - \sum_{i=1}^{n} (-1)^{i-1}h_{im} \end{pmatrix},$$

It is not hard to verify by (16) that Steffensen's condition (14) is satisfied for each column of S.

It is obvious that

$$\mathbf{S}^{T} = \begin{pmatrix} h_{11} & -h_{21} & h_{31} & -h_{41} & \cdots & (-1)^{n-1}h_{n1} & 1 - \sum_{i=1}^{n} (-1)^{i-1}h_{i1} \\ h_{12} & -h_{22} & h_{32} & -h_{42} & \cdots & (-1)^{n-1}h_{n2} & 1 - \sum_{i=1}^{n} (-1)^{i-1}h_{i2} \\ \vdots & \vdots & \vdots & \vdots & \cdots & \vdots & \vdots \\ h_{1m} & -h_{2m} & h_{3m} & -h_{4m} & \cdots & (-1)^{n-1}h_{nm} & 1 - \sum_{i=1}^{n} (-1)^{i-1}h_{im} \end{pmatrix}.$$

It now follows from Theorem D applied to the  $1 \times (n+1)$  monotonic vector  $(x_1, \ldots, x_n, 0)$  that

$$\sum_{j=1}^{m} b_{j} f\left(\sum_{i=1}^{n} (-1)^{i-1} h_{ij} x_{i}\right)$$

$$\leq \sum_{i=1}^{n} \sum_{j=1}^{m} b_{j} (-1)^{i-1} h_{ij} f(x_{i}) + \sum_{j=1}^{m} b_{j} \left(1 - \sum_{i=1}^{n} (-1)^{i-1} h_{ij}\right) f(0)$$

$$(17)$$

with

$$a_i = \sum_{j=1}^m b_j (-1)^{i-1} h_{ij}$$
 for  $i = 1, ..., n$ , and  $a_{n+1} = \sum_{j=1}^m b_j \left( 1 - \sum_{i=1}^n (-1)^{i-1} h_{ij} \right)$ .

Since  $b_j \ge 0$  for j = 1, ..., m,  $f(0) \le 0$  and  $1 - \sum_{i=1}^{n} (-1)^{i-1} h_{ij} \ge 0$  (see (5)), we get

$$\sum_{i=1}^{m} b_{j} \left( 1 - \sum_{i=1}^{n} (-1)^{i-1} h_{ij} \right) f(0) \le 0.$$

Therefore the right hand side of inequality (17) is estimated by upper bound

$$\sum_{i=1}^{n} \sum_{j=1}^{m} b_j (-1)^{i-1} h_{ij} f(x_i).$$

Thus we obtain a generalization of Brunk inequality (cf. Example 1.1):

$$\sum_{i=1}^{m} b_{j} f\left(\sum_{i=1}^{n} (-1)^{i-1} h_{ij} x_{i}\right) \leq \sum_{i=1}^{n} \sum_{j=1}^{m} b_{j} (-1)^{i-1} h_{ij} f(x_{i}).$$

$$(18)$$

In particular, when **H** is the matrix of ones, that is,  $h_{ij} = 1$  for i = 1, ..., n and j = 1, ..., m, then we get a Bellman like inequality:

$$\sum_{j=1}^{m} b_j f\left(\sum_{i=1}^{n} (-1)^{i-1} x_i\right) \le \sum_{i=1}^{n} \sum_{j=1}^{m} b_j (-1)^{i-1} f(x_i)$$
(19)

with

$$a_i = \sum_{i=1}^m b_i (-1)^{i-1}$$
 for  $i = 1, ..., n$ .

We also conclude that the resignation from the assumption  $f(0) \le 0$  leads to inequality (17), only, which corresponds to an Olkin's result [17] (see Example 1.1).

Note that one of the main assumptions of Theorem D is the *non-negativity* of the weights  $b_j$ . The purpose of the present paper is to extend this theorem to some other classes of weights by employing the above-mentioned Steffensen's condition (3).

The paper is arranged in the folowing way. In Section 1 we collect some needed terminology, definitions and facts. In Example 1.1, Brunk, Olkin and Bellman's inequalities are also presented. In Theorem D we demonstrate a Sherman-Steffensen type inequality with non-negative coefficients  $b_j$ , j = 1, ..., m. As consequence, we show a multivariate Brunk like inequality (see Example 1.3).

In Section 2 we establish the property of superadditivity of the Jensen-Steffensen functional (see Theorem 2.1). Here the main assumption is Steffensen's condition for some real l-tuple prepared by total sums of all entries of the involved coefficient vectors  $\mathbf{p}_1, \mathbf{p}_2, \dots, \mathbf{p}_l$  in  $\mathbb{R}^n$ . The case l = 2 leads to some resuls due to Barić et al. [2] and to Krnić et al. [11], and gives the monotonicity of the functional (see Corollary 2.4).

In Section 3 we investigate the Sherman-Steffensen type inequality for possibly negative coefficients  $b_j$ s. To do so, we employ the property of monotonicity of the Jensen-Steffensen functional. Again, the basic assumptions in Theorem 3.1 are Steffensen's conditions:

- (i) for the last column of the matrix,
- (ii) for the pairs of the total sums of entries of any column and of its difference with the next column of the matrix,
- (iii) for the difference of any two successive columns of the matrix.

Finally, we also apply  $n \times m$  row graded matrices in order to simplify conditions ensuring the validity of the inequality.

# 2. Superadditivity of the Jensen-Steffensen functional

For a function  $f: I \to \mathbb{R}$  on an interval  $I \subset \mathbb{R}$ ,  $\mathbf{x} \in I^n$  and  $\mathbf{p} \in \mathbb{R}^n$  with  $P_n = \langle \mathbf{p}, \mathbf{e} \rangle \neq 0$ , we define the Jensen-Steffensen functional by

$$J(f, \mathbf{x}, \mathbf{p}) = \langle \mathbf{p}, f(\mathbf{x}) \rangle - \langle \mathbf{p}, \mathbf{e} \rangle f\left(\frac{\langle \mathbf{p}, \mathbf{x} \rangle}{\langle \mathbf{p}, \mathbf{e} \rangle}\right). \tag{20}$$

Here we *do not assume* that  $\mathbf{p}$  is non-negative n-tuple.

We begin this section with a complement to Theorem B, which also extends a result of Krnić et al. [11, Theorem 2.1]. A consequence of Theorem 2.1 is Corollary 2.4 that will be used in the proofs of Theorems 3.1-3.2.

**Theorem 2.1.** Let  $f: I \to \mathbb{R}$  be a convex function on an interval  $I \subset \mathbb{R}$ . Let  $\mathbf{e} = (1, 1, ..., 1) \in \mathbb{R}^n$  and  $\mathbf{p}_1, \mathbf{p}_2, ..., \mathbf{p}_l \in \mathbb{R}^n$  be such that  $\langle \mathbf{p}_j, \mathbf{e} \rangle \neq 0$  for j = 1, ..., l, and

$$\sum_{j=1}^{l} \langle \mathbf{p}_{j}, \mathbf{e} \rangle > 0 \quad and \quad \sum_{j=1}^{l} \langle \mathbf{p}_{j}, \mathbf{e} \rangle \ge \sum_{j=1}^{i} \langle \mathbf{p}_{j}, \mathbf{e} \rangle \ge 0 \quad for \ i = 1, \dots, l.$$
 (21)

Then for any monotonic n-tuple  $\mathbf{x} \in I^n$ ,

$$\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{e} \rangle f \left( \frac{\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{e} \rangle} \right) \leq \sum_{i=1}^{l} \langle \mathbf{p}_{i}, \mathbf{e} \rangle f \left( \frac{\langle \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \mathbf{p}_{i}, \mathbf{e} \rangle} \right). \tag{22}$$

Moreover, the Jensen-Steffensen functional, under Steffensen's condition (21), is superadditive, i.e., (22) takes the equivalent form

$$J\left(f, \mathbf{x}, \sum_{i=1}^{l} \mathbf{p}_i\right) \ge \sum_{i=1}^{l} J(f, \mathbf{x}, \mathbf{p}_i). \tag{23}$$

**Proof**. The following identity holds

$$\frac{\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{e} \rangle} = \sum_{i=1}^{l} w_{i} \frac{\langle \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \mathbf{p}_{i}, \mathbf{e} \rangle},$$
(24)

where

$$w_i = \frac{\langle \mathbf{p}_i, \mathbf{e} \rangle}{\sum\limits_{j=1}^{L} \langle \mathbf{p}_j, \mathbf{e} \rangle} \quad \text{for } i = 1, \dots, l.$$
 (25)

Since  $f: I \to \mathbb{R}$  is convex on I, and  $1 = W_l \ge W_i \ge 0$  for i = 1, ..., l (see (21)), where

$$W_i = \sum_{j=1}^i w_j = \sum_{j=1}^i \frac{\langle \mathbf{p}_j, \mathbf{e} \rangle}{\sum\limits_{j=1}^l \langle \mathbf{p}_j, \mathbf{e} \rangle} \quad \text{for } i = 1, \dots, l,$$

by Jensen-Steffensen's inequality (see Theorem A) one has

$$f\left(\frac{\left\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{x} \right\rangle}{\left\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{e} \right\rangle}\right) = f\left(\sum_{i=1}^{l} w_{i} \frac{\langle \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \mathbf{p}_{i}, \mathbf{e} \rangle}\right) \leq \sum_{i=1}^{l} w_{i} f\left(\frac{\langle \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \mathbf{p}_{i}, \mathbf{e} \rangle}\right)$$

$$= \sum_{i=1}^{l} \frac{\langle \mathbf{p}_{i}, \mathbf{e} \rangle}{\sum\limits_{j=1}^{l} \langle \mathbf{p}_{j}, \mathbf{e} \rangle} f\left(\frac{\langle \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \mathbf{p}_{i}, \mathbf{e} \rangle}\right) = \frac{1}{\sum\limits_{j=1}^{l} \langle \mathbf{p}_{j}, \mathbf{e} \rangle} \sum_{i=1}^{l} \langle \mathbf{p}_{i}, \mathbf{e} \rangle f\left(\frac{\langle \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \mathbf{p}_{i}, \mathbf{e} \rangle}\right). \tag{26}$$

Now, it is not hard to see that (26) implies (22).

By using the notation (20) for the Jensen-Steffensen functional, we have

$$\sum_{i=1}^{l} J(f, \mathbf{x}, \mathbf{p}_i) = \sum_{i=1}^{l} \langle \mathbf{p}_i, f(\mathbf{x}) \rangle - \sum_{i=1}^{l} \langle \mathbf{p}_i, \mathbf{e} \rangle f\left(\frac{\langle \mathbf{p}_i, \mathbf{x} \rangle}{\langle \mathbf{p}_i, \mathbf{e} \rangle}\right)$$

and

$$J\left(f, \mathbf{x}, \sum_{i=1}^{l} \mathbf{p}_{i}\right) = \langle \sum_{i=1}^{l} \mathbf{p}_{i}, f(\mathbf{x}) \rangle - \langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{e} \rangle f\left(\frac{\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{x} \rangle}{\langle \sum_{i=1}^{l} \mathbf{p}_{i}, \mathbf{e} \rangle}\right).$$

Therefore (22) can be restated as

$$J\left(f,\mathbf{x},\sum_{i=1}^{l}\mathbf{p}_{i}\right)\geq\sum_{i=1}^{l}J(f,\mathbf{x},\mathbf{p}_{i}),$$

as claimed.

**Remark 2.2.** In context of Theorem 2.1, if the coefficient vectors  $\mathbf{p}_1, \mathbf{p}_2, \dots, \mathbf{p}_l \in \mathbb{R}^n$  have non-negative entries with positive sums, then the requirement (21) holds valid. Thus Theorem 2.1 is a generalization of Theorem B.

**Remark 2.3.** Observe that the requirement (21) can be viewed as the Steffensen's condition related to the *l*-tuple

$$(\langle \mathbf{p}_1, \mathbf{e} \rangle, \langle \mathbf{p}_2, \mathbf{e} \rangle, \dots, \langle \mathbf{p}_l, \mathbf{e} \rangle).$$

The next discussion concerns the monotonicity property (30) of the Jensen-Steffensen functional  $\mathbf{p} \to J(f, \mathbf{x}, \mathbf{p})$ . To this end, a sufficient condition is (27), which relaxes the standard requirement  $\mathbf{p} \ge \mathbf{q}$  with  $\langle \mathbf{p}, \mathbf{e} \rangle > 0$ ,  $\langle \mathbf{q}, \mathbf{e} \rangle > 0$  and  $p_i, q_i \ge 0$  (cf. [2, 11]).

**Corollary 2.4 (Cf. Barić et al. [2], Krnić et al. [11, Theorem 2.1]).** *Let*  $f : I \to \mathbb{R}$  *be a convex function on an interval*  $I \subset \mathbb{R}$ *. Let*  $\mathbf{e} = (1, 1, ..., 1) \in \mathbb{R}^n$  *and*  $\mathbf{p}, \mathbf{q} \in \mathbb{R}^n$  *be such that* 

$$P_n = \langle \mathbf{p}, \mathbf{e} \rangle > 0, \quad Q_n = \langle \mathbf{q}, \mathbf{e} \rangle > 0 \quad and \quad P_n - Q_n = \langle \mathbf{p} - \mathbf{q}, \mathbf{e} \rangle > 0.$$
 (27)

Then for any monotonic n-tuple  $\mathbf{x} \in I^n$ ,

$$J(f, \mathbf{x}, \mathbf{p}) \ge J(f, \mathbf{x}, \mathbf{p} - \mathbf{q}) + J(f, \mathbf{x}, \mathbf{q}). \tag{28}$$

If in addition the entries of p - q fulfill the Steffensen's condition, that is,

$$P_n - Q_n > 0$$
 and  $P_n - Q_n \ge P_i - Q_i \ge 0$  for  $i = 1, ..., n$ , (29)

then for any monotonic n-tuple  $\mathbf{x} \in I^n$ ,

$$J(f, \mathbf{x}, \mathbf{p}) \ge J(f, \mathbf{x}, \mathbf{q}). \tag{30}$$

Proof. We denote

$$\mathbf{p}_1 = \mathbf{p} - \mathbf{q}$$
 and  $\mathbf{p}_2 = \mathbf{q}$ .

Then via (27) we have

$$\langle \mathbf{p}_1 + \mathbf{p}_2, \mathbf{e} \rangle > 0$$
 and  $\langle \mathbf{p}_1 + \mathbf{p}_2, \mathbf{e} \rangle \ge \langle \mathbf{p}_1, \mathbf{e} \rangle \ge 0$ .

It now follows from Theorem 2.1 for l = 2 that

$$J(f, \mathbf{x}, \mathbf{p}_1 + \mathbf{p}_2) \ge J(f, \mathbf{x}, \mathbf{p}_1) + J(f, \mathbf{x}, \mathbf{p}_2),$$
 (31)

i.e.,

$$J(f, \mathbf{x}, \mathbf{p}) \ge J(f, \mathbf{x}, \mathbf{p} - \mathbf{q}) + J(f, \mathbf{x}, \mathbf{q}),$$

as was to be proved.

Assume in addition that (29) holds, that is, the entries of  $\mathbf{p}_1 = \mathbf{p} - \mathbf{q}$  fulfill the Steffensen's condition. Then we get  $J(f, \mathbf{x}, \mathbf{p}_1) \ge 0$  (see Theorem A). For this reason, (31) gives

$$I(f, \mathbf{x}, \mathbf{p}_1 + \mathbf{p}_2) \ge I(f, \mathbf{x}, \mathbf{p}_2).$$

In other words,

$$I(f, \mathbf{x}, \mathbf{p}) \ge I(f, \mathbf{x}, \mathbf{q}),$$

completing the proof.

**Remark 2.5.** Likewise in Remark 2.3, the restriction (27) is the Steffensen's condition related to the pair  $(\langle p - q, e \rangle, \langle q, e \rangle)$ .

## 3. Sherman - Steffensen like inequalities with possibly negative coefficients $b_i$

We now give another result of Sherman-Steffensen type, where the non-negativity of the coefficients  $b_i$  is relaxed at the expense of restricting the matrix **G**.

For an  $n \times m$  matrix  $\mathbf{G} = (g_{ij})$  we denote the ith sum of the jth column by  $G_{ij} = \sum_{k=1}^{n} g_{kj}$  for i = 1, 2, ..., n, j = 1, 2, ..., m. The jth column sum of  $\mathbf{G}$  is denoted by  $G_{nj} = \sum_{k=1}^{n} g_{kj}$ . The symbol  $\mathbf{g}_{j}$  stands for the jth column

**Theorem 3.1.** Let  $f: I \to \mathbb{R}$  be a convex function on an interval  $I \subset \mathbb{R}$ . Let  $\mathbf{x} = (x_1, x_2, ..., x_n) \in I^n$ ,  $\mathbf{y} = (y_1, y_2, ..., y_m) \in I^m$ ,  $\mathbf{a} = (a_1, a_2, ..., a_n) \in \mathbb{R}^n$  and  $\mathbf{b} = (b_1, b_2, ..., b_m) \in \mathbb{R}^m$ . Denote  $B_j = b_1 + b_2 + ... + b_j$  for j = 1, 2, ..., m.

$$B_j \ge 0, \quad j = 1, 2, \dots, m,$$
 (32)

$$\mathbf{x}$$
 is monotonic, (33)

and

of **G** for j = 1, 2, ..., m.

$$\mathbf{y} = \mathbf{x}\mathbf{G} \quad and \quad \mathbf{a} = \mathbf{b}\mathbf{G}^T \tag{34}$$

for some  $n \times m$  matrix  $G = (q_{ij})$  satisfying

$$G_{nm} > 0$$
 and  $G_{nm} \ge G_{im} \ge 0$ ,  $i = 1, ..., n$ , (35)

$$G_{nj} > 0$$
 and  $G_{n,j+1} > 0$ ,  $j = 1, ..., m-1$ , (36)

$$G_{nj} - G_{n,j+1} > 0$$
 and  $G_{nj} - G_{n,j+1} \ge G_{ij} - G_{i,j+1} \ge 0$ ,  $i = 1, ..., n, j = 1, ..., m - 1$ , (37)

then

$$\sum_{i=1}^{m} b_j G_{nj} f\left(\frac{y_j}{G_{nj}}\right) \le \sum_{i=1}^{n} a_i f(x_i). \tag{38}$$

**Proof.** Remind that the Jensen-Steffensen functional corresponding to the *j*th column  $\mathbf{g}_i$  of  $\mathbf{G}$  is given by

$$J(f, \mathbf{x}, \mathbf{g}_j) = \sum_{i=1}^n g_{ij} f(x_i) - G_{nj} f\left(\frac{1}{G_{nj}} \sum_{i=1}^n g_{ij} x_i\right) \quad \text{for } j = 1, 2, \dots, m.$$
(39)

We shall prove with the aid of condition (32) that

$$\sum_{j=1}^{m} b_j J(f, \mathbf{x}, \mathbf{g}_j) \ge 0. \tag{40}$$

To see this we invoke to Abel's identity

$$\sum_{j=1}^{m} b_{j} J(f, \mathbf{x}, \mathbf{g}_{j}) = \sum_{j=1}^{m-1} \left( J(f, \mathbf{x}, \mathbf{g}_{j}) - J(f, \mathbf{x}, \mathbf{g}_{j+1}) \right) B_{j} + J(f, \mathbf{x}, \mathbf{g}_{m}) B_{m}.$$
(41)

By using (35) and Jensen-Steffensen's inequality (see Theorem A), we obtain

$$G_{nm}f\left(\sum_{i=1}^n \frac{g_{im}}{G_{nm}}x_i\right) \leq \sum_{i=1}^n g_{im}f(x_i).$$

In other words, we have

$$J(f, \mathbf{x}, \mathbf{g}_m) \ge 0. \tag{42}$$

Furthermore, by (32) and (42) we have

$$J(f, \mathbf{x}, \mathbf{g}_m)B_m \ge 0. \tag{43}$$

By (36)-(37) we have

$$G_{nj} > 0$$
,  $G_{n,j+1} > 0$  and  $G_{nj} - G_{n,j+1} > 0$ ,  $j = 1, ..., m-1$ . (44)

In light of (37), (44) and Corollary 2.4 applied to  $\mathbf{g}_j$  and  $\mathbf{g}_{j+1}$ , we see that

$$J(f, \mathbf{x}, \mathbf{g}_i) \ge J(f, \mathbf{x}, \mathbf{g}_{i+1}) \text{ for } i = 1, 2, \dots, m-1.$$
 (45)

By combining (32), (41), (43) and (45), we deduce that (40) is satisfied, as claimed. We now deduce from (39) and (40) that

$$\sum_{j=1}^{m} b_{j} G_{nj} f\left(\frac{1}{G_{nj}} \sum_{i=1}^{n} g_{ij} x_{i}\right) \leq \sum_{j=1}^{m} b_{j} \sum_{i=1}^{n} g_{ij} f(x_{i}) = \sum_{i=1}^{n} \sum_{j=1}^{m} b_{j} g_{ij} f(x_{i}).$$

$$(46)$$

It follows from the first equality of (34) that  $(y_1, y_2, \dots, y_m) = (x_1, x_2, \dots, x_n)\mathbf{G}$ . That is,  $y_j = \sum_{i=1}^n g_{ij}x_i$ ,  $j = 1, 2, \dots, m$ . The second equality of (34) gives  $a_i = \sum_{j=1}^m b_j g_{ij}$ ,  $i = 1, 2, \dots, n$ . So, we find from (46) that

$$\sum_{i=1}^{m} b_j G_{nj} f\left(\frac{y_j}{G_{nj}}\right) \leq \sum_{i=1}^{n} a_i f(x_i),$$

which completes the proof of inequality (38).

We now discuss some simplifications of the assumptions in Theorem 3.1.

**Theorem 3.2.** *Under the assumptions of Theorem 3.1 with the condition (37) replaced by* 

$$G_{nj} - G_{n,j+1} > 0, \quad j = 1, \dots, m-1,$$
 (47)

then

$$\sum_{j=1}^{m-1} B_j J(f, \mathbf{x}, \mathbf{g}_j - \mathbf{g}_{j+1}) + \sum_{j=1}^m b_j G_{nj} f\left(\frac{y_j}{G_{nj}}\right) \le \sum_{i=1}^n a_i f(x_i).$$
(48)

**Proof**. We proceed as in the proof of Theorem 3.1. We apply the Abel's identity

$$\sum_{j=1}^{m} b_{j} J(f, \mathbf{x}, \mathbf{g}_{j}) = \sum_{j=1}^{m-1} \left( J(f, \mathbf{x}, \mathbf{g}_{j}) - J(f, \mathbf{x}, \mathbf{g}_{j+1}) \right) B_{j} + J(f, \mathbf{x}, \mathbf{g}_{m}) B_{m}.$$
(49)

By virtue of (35) and of Jensen-Steffensen inequality (see Theorem A), we obtain

$$J(f, \mathbf{x}, \mathbf{g}_m) = \sum_{i=1}^n g_{im} f(x_i) - G_{nm} f\left(\frac{1}{G_{nm}} \sum_{i=1}^n g_{im} x_i\right) \ge 0.$$
 (50)

By (32) and (50),

$$J(f, \mathbf{x}, \mathbf{g}_m)B_m \ge 0. \tag{51}$$

From (35) and (47) we have

$$G_{nj} > 0$$
,  $G_{n,j+1} > 0$  and  $G_{nj} - G_{n,j+1} > 0$ ,  $j = 1, ..., m-1$ . (52)

It now follows from (52) and Corollary 2.4 that

$$J(f, \mathbf{x}, \mathbf{g}_j) \ge J(f, \mathbf{x}, \mathbf{g}_{j+1}) + J(f, \mathbf{x}, \mathbf{g}_j - \mathbf{g}_{j+1}) \quad \text{for } j = 1, 2, \dots, m-1.$$
 (53)

By making use of (32), (49), (51) and (53) we infer that

$$\sum_{j=1}^{m} b_{j} J(f, \mathbf{x}, \mathbf{g}_{j}) \ge \sum_{j=1}^{m-1} \left( J(f, \mathbf{x}, \mathbf{g}_{j}) - J(f, \mathbf{x}, \mathbf{g}_{j+1}) \right) B_{j} \ge \sum_{j=1}^{m-1} J(f, \mathbf{x}, \mathbf{g}_{j} - \mathbf{g}_{j+1}) B_{j}.$$
 (54)

Therefore,

$$\sum_{j=1}^{m-1} J(f, \mathbf{x}, \mathbf{g}_j - \mathbf{g}_{j+1}) B_j + \sum_{j=1}^m b_j G_{nj} f\left(\frac{1}{G_{nj}} \sum_{i=1}^n g_{ij} x_i\right)$$

$$b_i \sum_{j=1}^n g_{ij} f(\mathbf{x}) = \sum_{j=1}^n \sum_{i=1}^m b_i g_{ij} f(\mathbf{x})$$

$$\leq \sum_{j=1}^{m} b_j \sum_{i=1}^{n} g_{ij} f(x_i) = \sum_{i=1}^{n} \sum_{j=1}^{m} b_j g_{ij} f(x_i).$$
 (55)

Moreover, by (34) we have  $y_j = \sum_{i=1}^{n} g_{ij}x_i$ , j = 1, ..., m, and  $a_i = \sum_{j=1}^{m} b_jg_{ij}$ , i = 1, ..., n. Finally, from (55) we get

$$\sum_{j=1}^{m-1} J(f, \mathbf{x}, \mathbf{g}_j - \mathbf{g}_{j+1}) B_j + \sum_{j=1}^{m} b_j G_{nj} f\left(\frac{y_j}{G_{nj}}\right) \le \sum_{i=1}^{n} a_i f(x_i),$$

completing the proof of (48).

Remark 3.3. Under the full condition (37), the Jensen-Steffensen functionals

$$J(f, \mathbf{x}, \mathbf{g}_j - \mathbf{g}_{j+1}), \quad j = 1, \dots, m-1$$

are non-negative (see Theorem A). Then (48) in Theorem 3.2 is a refinement of inequality (38) in Theorem 3.1. Conversely, with (47) in place of (37), the Jensen-Steffensen functionals can be negative in (48).

To give further simplifications of Theorem 3.2, we introduce row graded matrices, as follows. A real  $n \times m$  matrix  $G = (g_{ij})$  is said to be *row graded* if

$$g_{ij} \ge g_{i,j+1}$$
 for  $i = 1, 2, ..., n, j = 1, 2, ..., m - 1.$  (56)

For a row graded matrix  $\mathbf{G} = (g_{ij})$ , the vector  $\mathbf{g}_j - \mathbf{g}_{j+1}$  for j = 1, ..., m-1, has non-negative entries. As a result, condition (47) implies (37), so the Jensen-Steffensen functional  $J(f, \mathbf{x}, \mathbf{g}_j - \mathbf{g}_{j+1}) \ge 0$  is non-negative. Therefore we obtain

**Corollary 3.4.** *Under the assumptions of Theorem 3.1 with the condition (37) replaced by* 

$$G_{nj} - G_{n,j+1} > 0, \quad j = 1, \dots, m-1,$$
 (57)

for a row graded matrix **G**, then

$$\sum_{i=1}^{m} b_{j} G_{nj} f\left(\frac{y_{j}}{G_{nj}}\right) \leq \sum_{i=1}^{m-1} B_{j} J(f, \mathbf{x}, \mathbf{g}_{j} - \mathbf{g}_{j+1}) + \sum_{i=1}^{m} b_{j} G_{nj} f\left(\frac{y_{j}}{G_{nj}}\right) \leq \sum_{i=1}^{n} a_{i} f(x_{i}).$$
 (58)
